5.Implementation of K-Means Clustering

Aim :

To write a program that implements the K-Means clustering algorithm to group the given data points into k clusters based on their similarity, and to display the cluster labels, the cluster centroids and a plot of the resulting clusters.

Algorithm :

1. Start the program.
2. Import the required libraries (pandas, numpy, matplotlib, and KMeans from sklearn.cluster).
3. Load the dataset from the input file.
4. Select the input features to be used for clustering (no target variable is needed, since clustering is unsupervised).
5. Choose the number of clusters k (for example k = 3).
6. Create the KMeans model with k clusters and a fixed random_state.
7. Randomly initialize k centroids.
8. Assign each data point to the nearest centroid using Euclidean distance.
9. Recalculate each centroid as the mean of all the data points assigned to that cluster.
10. Repeat steps 8 and 9 until the centroids no longer change or the maximum number of
iterations is reached.
11. Fit the model on the data and obtain the cluster label for each data point.
12. Display the cluster labels and the final cluster centroids.
13. Plot the data points coloured by cluster, along with the centroids.
14. Stop the program.

Program&Result&Graph:
